

RTMcompare

Nine surfaces. One master volume.

Every feature in RTMcompare 5.3.0, in plain language.
No marketing rounding-up — if a row is here, the
feature is in the build you can install today.

Surface by surface. One feature per row. Skim it,
tick the bits you care about, ignore the rest.

A/B Compare.

Two files in. Every measurable difference out.

Level-matched playback

Both files normalise to -18 LUFS before you hear them. Loud doesn't get to fake good.

LUFS-I, TP, LRA, MONO

The four numbers every delivery checks. Top of every screen, no digging.

Per-band masking

Demucs AI splits the stems first, then we show where vocals, drums, bass and the rest lose energy — per band. Whole-mix masking misses the interesting stuff.

Phase correlation over time

Full-track plot plus a per-band ribbon. Catches phase trouble that one big "+0.92" number sails past.

Vectorscope

XY mid/side scope with peak-hold. Width and centre-energy at a glance.

Streaming-normalisation preview

Spotify, Apple, Amazon, Tidal, YouTube — hear what your master sounds like AFTER each platform turns it down.

Inter-sample peak meter

True-peak with 16× oversampling. Your DAW's master meter doesn't catch these. We do.

AAC encode preview

Run your master through Apple's actual AAC encoder. Hear the lossy version against the original.

Engineer-profile matching

Serban Ghenea, Chris Lord-Alge, or your own (built with RTMprofile from your finished work). Match score, plus the exact EQ moves to close the gap.

EQ-move export

Export to FabFilter Pro-Q, CSV, or JSON. Or skip the EQ entirely — let RTMcompare bounce the corrected master itself in one click.

Single-File QC.

Drop one file. Get a thorough check-up.

Click + glitch timeline

Every click and glitch plotted on a timeline. Click any peak — playback jumps right there. Audit a record in minutes.

Distortion detection

Clipping, inter-sample, harmonic. Each one tagged with severity and the band it lives in. No red blobs.

Mains hum + harmonics

50 or 60 Hz fundamental, plus 3rd, 5th and 7th harmonics. Spots a ground loop in seconds.

Limiter artefact detection

Pumping, intermodulation, stuck-fast release, pre-ring. Severity-rated. Tells you when the limiter is doing harm, not just work.

Transfer-artefact detection

Wow, flutter, DC drift, tape transport, print-through. The whole analog-source rogue's gallery.

Generation-loss detection

AAC or MP3 fingerprints hiding inside what someone called "the original." We see them.

Key, BPM, harmonic ladder

For sync pitching and clean metadata. (No more guessing the BPM yourself.)

Dialog gate metering

For post-produced and spoken-word masters: dialog presence detection and per-region loudness on the speech bands only.

Mono-compatible waterfall

Per band, not one big number. See exactly where the mono fold falls apart.

Stereo image + phase bands

Width on one axis, per-band phase on the other. The whole stereo picture, side by side.

Album Batch + Cohort.

A folder in. A sortable table out. Drift detection across the album.

Sortable overview table

LUFS, TP, LRA, ISRC, duration, sample rate, bit depth — outliers flagged in red.

One rotating song tab

← → flips songs. Deep analysis runs once per song, then caches. No re-runs.

Per-song + album notes

Notes embedded in every PDF export. They travel with the album.

.rtmalbum.json sessions

One file holds every analysis, every note, every reference, the delivery state. Re-open it in a year.

Cohort heatmap

31-band distance per track. Sort by drift, find the song that doesn't belong.

RMS distance column

One ranked number for "how consistent is this album." The honest answer.

Atmos and immersive.

Validates the immersive master before delivery.

ADM BWF parsing

Bed channels, objects, trajectories, layout. All four read.

Binaural TP metering

Apple's Atmos delivery wants < -1 dBTP on the binaural render. We measure it.

Atmos Preflight hard-checks

Objects ≥ 118 , LFE routed, bed layout (7.1.2 or 5.1.4), 48 kHz, ≥ 24 -bit. Anything fails, the export gates.

Per-object anomaly detection

Hot, silent, static, or dark objects. Almost always a mix mistake, not an artistic choice.

Stereo downmix QC

BS.775 fold-down compared against the immersive master. Catches downmix surprises before the platform does.

Quality, Player, Triage, Shell.

The verdict surfaces and the visual chrome.

AI-generation detection

Per-stem ML fingerprint detection. Spots AI-generated audio hiding in a mix.

Engineer-target curves

Match score against the engineer profile you picked.

Concrete EQ moves

Frequency, gain, Q — for every move. Export, or apply.

Apply-and-bounce

One click. The corrected WAV lands in your render folder.

A/B Player everywhere

Same player, same shortcuts on every screen. Space to play, A/B to flip, X to swap.

Live TP meter

Instant and 2-second peak-hold, right on the transport.

Triage Mode (optional)

A Ready-to-Deliver verdict, an Attention list, per-platform spec checks. Toggle on when you want it, off when you don't.

Console Didone Shell (5.2)

The new look: two-row header, big Didone numbers, one gold accent per screen.

v1 Classic shell

Prefer the old look? `localStorage[rtm-shell] = v1` brings back the 5.1.x layout, exactly.

RTMprofile companion

Standalone app. 5+ finished masters in, your engineer profile out.

RTMsend companion

VST3 / AU plugin. One button from your DAW into RTMcompare. ARA-aware where it counts.

COLOPHON

Built on.

The stack underneath.

Electron · React 19 · TypeScript · Tailwind v4 · Vite
Python 3.11 · NumPy · SciPy · librosa · pyloudnorm · Demucs
JUCE 7 (RTMsend) · electron-builder · electron-rebuild

Wordmark and hero numerals set in Instrument Serif.
Body and labels in Instrument Sans. Tabular data in
Geist Mono. Single antique-gold accent reserved for
the active delivery-target chip.
